

State Continued Claims

Phase 1 - Dataset Validation Report

Weekly state-level continued claims (insured unemployment), 50 states + DC
FRED/ALFRED point-in-time archive - validated for forecasting, lead-lag analysis and
backtesting

GATE STATUS: CLEARED with documented caveats

Dataset	{ABBR}CCLAIMS weekly NSA (DOL ETA via FRED); initial claims used for cross-checks
Coverage	Current history 1986-2026; ALFRED point-in-time archive Sep 2010 onward
Validated at	2026-07-08 11:06:50
Source suite	claims_validation.ipynb (self-contained; fetches all data from the FRED API)

Executive summary

This report validates the state-level continued-claims dataset before any modeling. The suite runs 43 checks across ten modules, each stated as a question about the data with an explicit pass criterion. The dataset is **cleared for use** subject to the gating rules below; every WARN is a documented caveat with a concrete handling rule, not an open issue.

Headline findings

- **The release calendar is verified.** Continued claims are published Thursdays 8:30 ET (96.7% of national vintages; 3.3% holiday-Wednesdays) for the reference week ending the Saturday 12 days earlier - continued claims trail initial claims by one week (V3.2, V3.3, V2.1).
- **FRED changed how it archives state claims in July 2020.** Pre-switch, ALFRED stores the *revised* print captured at week-ending +19d; post-switch, the *advance* (first, preliminary) print at +13d. Backtests must use per-era availability lags: the information set differs by a week across eras, and the print content differs too (V3.7).
- **State first prints are NOT negligibly revised.** 3.3% of weeks (1,402) were later corrected, concentrated in four chronic-reviser states (Hawaii, Pennsylvania, New Mexico, Maryland = 56% of exceptions) and the 2020-22 pandemic window, plus isolated digit errors - e.g. Texas 2024-06 published 48,748 instead of 148,748 (V4.1, V5.4).
- **The advance-vs-revised gap is small.** Calibrated on the national series: median -0.1%, IQR +/-0.3% - so the July-2020 print-type mixing is second-order for state features (V4.3).
- **No look-ahead anywhere.** Minimum state availability lag is 13 days - after the public report; the point-in-time panel passes a hard look-ahead guard on all 41,667 rows (V3.6, V3.9).
- **Strong NSA seasonality and holiday mechanics.** ACF(52) median 0.64; holiday weeks shift log changes by +0.11. Work in YoY log-differences with holiday controls or 4-week averages (V7).

Gate decisions

G1 - Scope cleared	Backtesting / point-in-time work: 2010-11-05 onward (51/51 PIT coverage, strict ALFRED vintages). Seasonality / climatology estimation: full 1986+ history with the documented rules (zeros treated as missing, no forward-fill through gaps, pre-1990 treated as a noisier startup era). Not cleared: treating pre-Sep-2010 data as point-in-time.
G2 - Required transforms	YoY log-differences (stationary) or weekly log-changes with week-of-year and holiday controls; 4-week moving-average features to suppress reporting noise; regime-flag 2020-21 (PUA/PEUC exclusion, CA frozen prints); winsorize week-over-week features against isolated first-print data errors.
G3 - Alignment rules	Index all information by release date (Friday as-of grid), never by observation week. Apply per-era staleness: revised print at Sat+19d before 2020-07-10, advance print at Sat+13d after (post-2020 tail to +16d on Monday ingestions). Carry a revised-later flag for the 1,402 exception weeks (claims_revision_exceptions.csv).

Maintained hypotheses and vocabulary

H1 - Publication schedule. Continued claims are released every Thursday at 8:30 AM ET in the DOL's Unemployment Insurance Weekly Claims report, jointly with initial claims (Wednesday when Thursday is a federal holiday). *Verified:* V3.2 (national vintage weekdays 96.7% Thu / 3.3% holiday-Wed), V3.3 (first release at the expected day count).

H2 - Reference period. The reference week ends on the Saturday two weeks prior to the release; continued claims lag initial claims by one week because a continued claim is only counted after the person certifies for the prior week's benefits. *Verified:* V2.1 (every observation date is a Saturday), V3.3 (release minus reference = exactly 12 days).

Advance print = the first, preliminary figure for a reference week, published in the Thursday report immediately after the certification week (DOL labels these columns 'Advance'). **Revised print** = the corrected figure one week later in the next report; essentially final for state series. The dataset stores revised prints before July 2020 and advance prints after (V3.7).

Two clocks. Every value carries an observation timestamp (the Saturday-ending week it measures, module V2) and an information timestamp (when it became known, module V3). All feature joins must use the information clock.

The two clocks on one concrete week: measured Saturday, public the second Thursday after (+12d), captured by FRED the next day (+13d), revised print one week later (+19d).

V1-V2 - Structural integrity and calendar (observation clock)

Universe, keys, parse consistency and the Saturday week-ending calendar. All structural checks pass: 51 states everywhere, zero duplicate keys, zero nulls, values parse cleanly across FRED's int-to-float format drift.

Key findings

- All values strictly positive and finite except 15 explicit zeros, all in Jan-Jul 1986 (V1.4).
- Zeros split 9 leading (benign ramp-in) vs 6 interior (dropouts) - all pre-1990 (V1.4b).
- Panel edges aligned: common balanced window 1986-02-08 to present (V2.3).

V1.4b - the 15 zero values in the 1986 startup window. Blue (leading) zeros precede a series' first real value; red (interior) zeros are dropouts inside live data - e.g. New Jersey July 1986: 13,777 / 0 / 0 / 7,846. Rule: treat values ≤ 0 as missing before any log transform.

V2.2 - missing reference weeks (observation clock). 48 gaps cluster in the 1986-88 startup era; the single modern gap is Virginia 2026-05-23 - a live issue to monitor for backfill.

V3 - Point-in-time integrity and release calendar (information clock)

The backtest-critical module: does the archive respect the real-world publication schedule, and is there any look-ahead? The leak check passes: the minimum state availability lag is 13 days, i.e. nothing is ever marked available before the DOL report that first contains it (V3.6). The PIT panel passes a hard look-ahead guard on all 41,667 rows (V3.9).

Key findings

- States and national are published simultaneously in the same Thursday report; the gaps measured here are FRED's archival schedule, making ALFRED capture dates a conservative availability assumption (V3.5).
- Backtest staleness assumption: Sat+19d pre-2020-07-10; Sat+13d typical / +16d conservative after (V9.3).
- Release dates are weakly increasing in observation order - the availability frontier is monotone (V3.8).

V3.7 - the capture-regime change. Weekly cross-state median capture lag steps from 19 days (revised print, captured on the following report day) to 13 days (advance print, captured the day after release) in July 2020. Red line = 12-day public-availability floor.

V3.7 - capture weekday: Thursday dominates the revised-print era, Friday the advance-print era; the small Monday share is FRED ingestion delay, not release timing.

V3.5b - state-minus-national capture gap by era. Pre-2020 is rock-solid at +7d (97.8% in-window); post-2020 is modal +1d with a ~13% Monday-slip mode (+4d). Negative gaps are the 7 weeks where the NATIONAL series was archived late - never states being public first.

V3.5b - in-window share by release year against the 95% consistency bar; the 2021 transition year is the outlier (~57% in-window).

V4 - Revision behavior: first release and after

How often does a first print change, where, and by how much? The endpoint join (first release vs current) finds 1,402 revised weeks - 3.3% of the panel, far from the near-zero rate a small-sample probe suggests. Full vintage trajectories confirm no hidden intermediate revisions in the five core states (0.46% multi-valued), while Hawaii revises up to 5 times per week - its first prints are genuinely preliminary.

Key findings

- The typical advance print slightly overstates claims (median revision -0.1%).
- Chronic-reviser states warrant state-specific noise handling or a revised-later flag feature (V4.1b).

V4.1 - revisions are concentrated: Hawaii (403), Pennsylvania (168), New Mexico (111), Maryland (104) account for 56% of all exceptions.

V4.1 - revision magnitudes over time: corrections cluster in 2020-22; isolated digit errors labeled (AZ 2026, VA 2021, TX 2024, ...).

National CCNSA: advance print -> revised print, one week later (% change, clipped +-3%)

V4.3 - the advance-to-revised gap calibrated on the national series: median -0.09%, IQR [-0.39%, +0.21%], tails to ~6% only in COVID weeks.
Verdict: the July-2020 print-type mixing is second-order; add an era dummy if precise levels matter.

V5 - Outliers, staleness and anomalies

Repeat-value runs, extreme moves and reporting artifacts. 1,477 extreme weekly moves classify almost entirely as COVID (224), holiday mechanics (732) or the pre-1990 startup era (167); 354 modern unexplained moves remain for eyeballing. Ohio reports rounded values (6% divisible by 100).

V5.1 - the flagship stale run: California's EDD processing pause froze first-release prints at 2,802,145 (flat dashed red) through late 2020 while the corrected history (blue) declined. A live model saw the frozen prints - treat as stale, not signal.

V5.4 - forensic case study, discovered by the V4.1 revision check: Texas week 2024-06-01 first published 48,748 (red X) - a dropped leading '1'; neighbors and the corrected value (148,748) are consistent. A strict PIT backtest used the erroneous print: winsorize WoW features or flag data errors.

V5.2 - all extreme weekly moves ($|robust\ z| > 6$) classified: COVID (crimson), holiday (orange), pre-1990 (gray), unexplained (purple).

V6 - Cross-sectional coherence

Do the states add up, and does every state co-move with the national cycle? Yes: the 51-state sum tracks national CCNSA at a median ratio of 0.986 (gap = Puerto Rico / Virgin Islands, excluded here) with a tight 0.007 IQR; the median pairwise YoY correlation is 0.89 and no state falls below the 0.30 quality floor.

V6.1 - sum of 51 states / national CCNSA over time.

V6.2 - mean pairwise correlation of YoY changes by state, all above the 0.30 floor.

V7 - Seasonality and stationarity (forecasting-critical)

State claims exist only NSA. Annual seasonality is strong (ACF at lag 52 of weekly log-changes: median 0.64 across states) and holiday weeks shift log-changes by +0.11 on average - both must be modeled. ADF tests confirm log levels are borderline/non-stationary while YoY log-differences are stationary ($p < 0.001$) in all sample states. Weekly persistence is high everywhere (AR(1) of log level: min 0.938).

Key findings

- COVID caveat: regular-state continued claims exclude PUA/PEUC - 2020-21 levels understate total insured unemployment; prefer changes or regime-flag the window (V7.5).

Week-of-year seasonal profile (demeaned log level, 2011-2019) for CA / TX / NY.

Seasonality strength: ACF(52) of weekly log-changes across all 51 states (2011-2019).

Persistence: AR(1) of weekly log level by state - minimum 0.938, all above the 0.90 tripwire.

V8-V9 - Lead-lag and backtest readiness

Wiring and information-set checks before any lead-lag analysis or backtest. The PIT panel is indexed on a Friday as-of grid (information time); orientation is correct - YoY claims changes correlate ~0.85-0.90 with YoY unemployment changes, peaking at $k=0$ months in all five sample states. The panel is complete (51/51 states) from 2010-11-05 with zero holes.

Key findings

- Weekly-to-monthly aggregation must respect the LAUS reference week (the week containing the 12th) - calendar-month averaging leaks post-reference information (V8.3).

V8.2 - cross-correlation profiles: $\text{corr}(\text{YoY dlog claims at } t, \text{YoY d(urate) at } t+k)$. Peaks at $k=0$ with corr 0.83-0.90 - signs and alignment are wired correctly. This validates wiring, not the lead-lag analysis itself.

V9.1 - PIT panel coverage: 51/51 states from 2010-11-05, no mid-sample holes.

V9.4 - share of PIT rows whose latest reading was later revised, by as-of year: 3.3% overall (6.8% counting anywhere in the 8-week window), concentrated in 2020-22 and chronic-reviser states.

Appendix A - Full check results

All checks with the question each answers, the measured value and the handling note. PASS = criterion met; WARN = usable with the documented rule; FAIL = blocker.

ID	Question	Result	Metric	Note / rule
V1.1	Do we have all 51 states in every table?	PASS	{'vintage': 51, 'current': 51, 'pit': 51}	
V1.2	Is (state, claim_type, week) a unique key?	PASS	vintage=0, current=0, pit=0	
V1.3	Are key fields complete (no nulls)?	PASS	0 nulls	
V1.4	Is every value parseable, finite and positive?	WARN	vintage bad=0; current zeros=15 (latest 1986-07-19), post-1990=0	all zeros sit in Jan-Jul 1986 — RULE: treat values <= 0 as missing before any log transform. FRED int->float format drift coerced cleanly. Position analysis in V1.4b.
V1.4b	Are zeros ramp-in artifacts (leading) or mid-sample dropouts (interior)?	WARN	9 leading, 6 interior; interior post-1990: 0	leading zeros = series ramp-in, drop silently; INTERIOR zeros are dropouts inside live data (e.g. NJ iclaims Jul-1986: 13,777 -> 0 -> 0 -> 7,846) — must be masked BEFORE differencing or the surrounding WoW changes are corrupted too
V1.5	Did any state's fetch silently truncate?	PASS	min=2099, max=2111	small raggedness at series start (states begin reporting a few weeks apart in 1986)
V2.1	Do obs dates follow the DOL Saturday week-ending convention?	PASS	0 non-Saturday	
V2.2a	Are there missing weeks in the pre-1990 history?	WARN	48 missing weeks across 22 states (1986-88)	early DOL collection holes — RULE: forecasting pipelines must handle NaN weeks; do not forward-fill through gaps when computing WoW changes
V2.2b	Are there missing weeks in modern data (live issues)?	WARN	Virginia 2026-05-23	a recent missing week = state failed to report / FRED shows '.' — monitor for backfill; PIT features skip the week automatically (availability frontier)
V2.3	Do all states cover the same window?	PASS	start spread=5w, end spread=0w	common balanced window: 1986-02-08 -> 2026-06-13
V3.1	How far back can point-in-time be reconstructed?	WARN	first vintage 2010-09-16	pre-boundary history (1986->2010-09) exists only as current values: usable for seasonality/climatology, NOT for backtesting
V3.2	Does the vintage calendar match the DOL mid-week release schedule?	PASS	Thu 96.7%, Wed 3.3% of 867 vintages	Wednesday releases are the holiday-shifted reports (Thanksgiving, Jul 4, ...)
V3.3	Is the national first release the advance print at obs+12d?	PASS	median lag 12d (min 11, max 61)	CC reference week trails the report by 12 days (one week behind initial claims)
V3.4	On which weekday does FRED capture state data?	PASS	Mon 4.9%, Tue 0.0%, Wed 1.3%, Thu 60.1%, Fri 33.6%	Mon captures are FRED ingestion delays, not release timing — see V3.5/V3.6
V3.5	How long after the public release do state values appear?	PASS	32.6% within 0-2d of national release; 61.2% at +6-8d (next report)	IMPORTANT: this measures FRED/ALFRED CAPTURE order, not DOL publication order. DOL publishes state and national figures SIMULTANEOUSLY in the same Thursday report — states are not released later, they are ARCHIVED later by FRED. +6-8d cluster = pre-2020 (state series archived one report cycle later, storing the revised print); 0-2d cluster = 2020+ (archived the day after the release, storing the advance print). For backtests, ALFRED capture dates are therefore a CONSERVATIVE availability assumption.
V3.5b	Is the state-vs-national gap pattern stable within each era?	WARN	pre-2020: 97.8% at +6-8d; post-2020: 83.6% at +0-2d (+12.7% slip to +3-5d = Monday ingestion)	pre-2020 is rock-solid (median gap +7d every year). post-2020 is modal +1d (Friday) but NOT fully consistent: ~10% of captures slip to Monday (+4d), and the 2021 transition year is chaotic (~57% in-window). Backtest staleness post-2020: 13d typical, 16d conservative (Monday-slip tail). Negative gaps in the histogram are the 7 late-NATIONAL-archive weeks (V3.6) — not states being published early.
V3.6	Could a backtest have seen state data before it was public?	PASS	min state pub lag 13d across all 42k vintage rows	a NAIVE version of this check (state date < national ALFRED date) fires 357 false alarms on 7 weeks — those are weeks where the NATIONAL series was archived late (ALFRED artifact), not early state data — a negative gap never means the state number was PUBLIC first; see example below
V3.7	Has FRED's capture timing / stored print type been stable?	WARN	switch ~2020-07-10: median 19d -> 13d	pre-switch ALFRED stores the REVISED print (captured Sat+19d, i.e. on the following report day); post-switch the ADVANCE print (captured Sat+13d, the day after release). Backtests MUST use per-era lags; the print content differs by era too.

ID	Question	Result	Metric	Note / rule
V3.8	Do weeks become available in order?	PASS	0 inversions	an inversion means a later week became visible before an earlier one — harmless if tiny, but the PIT builder must use the cummax frontier (it does)
V3.9	Does the PIT panel contain any look-ahead?	PASS	0 violations, 0 unmatched keys of 41,667 rows	
V4.1	How often does a first print get revised at all?	WARN	1402 of 42,074 obs revised (3.33%)	NOT the near-zero rate a small-sample probe suggests: revisions are real but concentrated — see the by-state and by-year breakdowns; full exception list feeds V9.4
V4.1b	Where are revisions concentrated?	WARN	top-4 states = 56% of exceptions: Hawaii n=403 (med [0.2%]), Pennsylvania n=168 (med [0.1%]), New Mexico n=111 (med [3.0%]), Maryland n=104 (med [0.1%])	chronic revisers publish systematically preliminary first prints — consider state-specific noise handling or a revised_later flag feature; 2020-22 corrections are pandemic-era admin fixes
V4.2	Do values change mid-life and net out (invisible to endpoint checks)?	PASS	core states: 49 multi-valued obs of 10,556 (0.46%); Hawaii: 405 of 2152 (up to 5 values per obs)	core states are (near-)single-valued across all vintages, so V4.1's endpoint join captures their revision behavior; Hawaii revises repeatedly (up to 5 values per week) — its first prints are genuinely preliminary
V4.3	How big is the national advance-to-revised gap?	PASS	median -0.09%, IQR [-0.39%, +0.21%], max [6.4%]	the typical advance->revised change is ~-0.1% (the advance slightly OVERSTATES claims), IQR +/-0.3%, tails ~6% in COVID weeks. VERDICT: the V3.7 era mixing (revised prints pre-2020 vs advance prints post-2020) is a second-order inconsistency for state features — acceptable; add an era dummy if precise levels matter.
V5.1	Are there frozen/stale stretches masquerading as data?	WARN	75 runs in current values; 34 in first-release values	known: CA late-2020 processing pause (EDD backlog) froze FIRST-RELEASE prints — visible in the vintage data even where current data was later corrected; treat runs as stale/missing, not signal
V5.2	Which extreme moves are real events vs calendar mechanics vs unexplained?	WARN	1477 extreme moves: 224 COVID, 732 holiday, 167 pre-1990 era, 354 unexplained modern	COVID moves are genuine macro events — keep but regime-flag; pre-1990 spikes reflect the noisier startup era (see V1.4/V2.2a); the modern unexplained list needs eyeballing before use
V5.3	Do some states report rounded numbers (noise floor)?	WARN	1 states > 5%: Ohio 6%	rounded reporting inflates the noise floor for those states — matters for WoW features
V5.4	Did the TX 2024-06 +100k first-print error really happen, and which print was wrong?	WARN	first=48,748, current=148,748, neighbors mean=148,270	first release was the data error (dropped leading digit); current value is credible. A strict PIT feature on ~2024-06-14 used the erroneous print — add a data-error dummy or winsorize WoW changes in backtests.
V6.1	Do the 51 states add up to the national total?	PASS	median ratio 0.986, IQR width 0.007, range [0.957, 1.188]	gap = PR/VI + timing; large transient deviations flag data problems in specific weeks
V6.2	Does every state co-move with the national cycle?	PASS	panel median 0.89; no state < 0.30	a state decorrelated from the national cycle is a data-quality suspect, not an alpha source
V7.1	How strong is the annual seasonality to handle?	WARN	median 0.64, min 0.17, max 0.85	use YoY transforms, 52-week differencing, or explicit week-of-year/holiday controls
V7.2	Are holiday weeks mechanically distorted?	WARN	holiday +0.100 vs regular -0.010 (spread +0.110 log-pts)	if WARN: add holiday dummies or use 4-week MA features (pit already includes 4wma)
V7.3	Which transform makes the series stationary?	PASS	California: lvl p=0.00, yoy p=0.000; Texas: lvl p=0.00, yoy p=0.000; New York: lvl p=0.00, yoy p=0.000; Florida: lvl p=0.07, yoy p=0.000; Michigan: lvl p=0.00, yoy p=0.000	work in YoY log-diff (or dlog with seasonal controls); levels are non-stationary
V7.4	Is persistence plausible in every state?	PASS	min 0.938 (New York), median 0.980	weekly insured-unemployment stocks are extremely persistent; a low-AR1 state = noisy/broken data
V7.5	What did continued claims exclude during COVID?	WARN	2020-2021 levels exclude PUA/PEUC	regular-state CC understates total insured unemployment during 2020-21; level-based cross-state comparisons in that window are biased — prefer changes or regime-flag it
V8.1	Are features indexed by information time?	PASS	all Fridays: True; median cclaims staleness 20d	
V8.2	Do claims lead unemployment with the right sign (wiring check)?	PASS	California: peak corr 0.89 at k=0m; Texas: peak corr 0.88 at k=0m; New York: peak corr 0.90 at k=0m; Florida: peak corr 0.87 at k=0m; Michigan: peak corr 0.83 at k=0m	validates sign/alignment wiring only — NOT the lead-lag analysis itself
V8.3	How must weekly claims map onto monthly reference periods?	WARN	LAUS reference week = week containing the 12th	when pairing claims with LAUS monthly data, align claims weeks to the reference week, not calendar-month averages (calendar averaging leaks post-reference-week info into the month)
V9.1	From which date is the PIT panel backtest-complete?	PASS	51/51 from 2010-11-05; 0 holes after that	usable backtest window starts 2010-11-05
V9.2	Is the universe stable (no entry/exit)?	WARN	weeks per state: 2099-2106	1-7 week differences = the interior gaps enumerated in V2.2 (pre-1990 + VA 2026)

ID	Question	Result	Metric	Note / rule
V9.3	What staleness must a backtest assume, per era?	WARN	{'post-switch': {'median': 13.0, 'min': 13, 'max': 27}, 'pre-switch': {'median': 20.0, 'min': 13, 'max': 27}}	apply per-era staleness — a constant-lag assumption misprices the pre-2020 era by ~1 week
V9.4	How many feature rows carry later-corrected values?	WARN	t0 revised-later: 1386 rows (3.3%); any of t0..t7: 2823 rows (6.8%)	strict PIT correctly keeps these (that is what was known at the time) — but they are error-prone inputs concentrated in chronic-reviser states and 2020-22; RECOMMENDATION: add a revised_later flag column to the feature panel and winsorize WoW features
V10.1	Can the dataset be reproduced and audited byte-for-byte?	PASS	claims_validation_manifest.json	ALFRED queries with pinned realtime_* params are reproducible; re-fetch and diff hashes to audit

Appendix B - Reproducibility and audit trail

The suite is self-contained: **claims_validation.ipynb** fetches every input from the FRED/ALFRED API (~205 calls, ~4 minutes) and rebuilds the dataset from scratch. ALFRED queries with pinned realtime parameters are reproducible - a re-fetch two days apart produced byte-identical CSVs (SHA-256 verified).

Validated at: 2026-07-08 11:06:50
